The first aim of this study is to evaluate the performance of Weather Research and Forecasting-Community Multiscale Air Quality (WRF-CMAQ) modeling system. Especially fine particulate matter (PM$_{2.5}$) concentrations and its components in Japan which are controlled by heavy local air pollution and long-range transport from East Asia are focused. The daily meteorological variations and the monthly atmospheric pollutants were well captured by the modeling system. PM$_{2.5}$ concentrations were affected from long-range transport from East Asia. Sulfate of PM$_{2.5}$ components was reasonably represented but organic aerosol was underestimated by the modeling system. The second aim of this study is to evaluate the impact of the aerosol direct effect on simulated concentrations of PM$_{2.5}$ over East Asia by using the online coupled WRF-CMAQ modeling system. The simulations showed there were particularly large impacts of the aerosol direct effect in the eastern Asian Continent with high aerosol loading. The largest temporal mean contributions of the direct effect were 40% decrease in the surface shortwave radiation, 30% decrease in the planetary boundary layer height, and 20% increase in the ground-level PM2.5 concentration in the continent.
